MOLYFILE – AN INDEX-LEVEL COMPUTER FILE OF MOLYBDENUM DEPOSITS AND OCCURRENCES IN CANADA

Abstract

MOLYFILE was constructed during the 1970s to ascertain the general nature and distribution of molybdenum deposits and occurrences in Canada, to support map and report production, and for metallogenetic and resource studies. The file contains information on: name(s), location, political province, geological province, geological age (if available), deposit type, major commodities, minor commodities, molybdenum status, reserves, and production. Lack of accurate reference and bibliographic data and uncertainty of locations of some deposits and occurrences are weaknesses of MOLYFILE. Despite these weaknesses the file provides a basic inventory of molybdenum deposits and occurrences in Canada and should be of particular use to exploration geologists, resource planners, and to individuals studying molybdenum deposits.

Résumé

Le dossier MOLYFILE a été créé au cours des années 1970 en vue de déterminer la nature et la distribution générales des gisements et venues de molybdène au Canada, d'appuyer la production de cartes et de rapports et de constituer une banque de données aux fins d'études sur les ressources et sur la formation des gîtes métallifères. Les dossier comprend des renseignements sur les noms, l'emplacement, la province, la province géologique, l'âge géologique (lorsque disponible), le type de gisement, les matières premières essentielles, les matières premières secondaires, la qualité du molybdène, les réserves et la production. Les points faibles de MOLYFILE sont les suivants: manque de références et de données bibliographiques précises, et de clarté dans la description de l'emplacement de certains gisements et venues. En dépit de ces lacunes, le dossier fournit un inventaire de base des gisements et venues de molybdène au Canada et devrait être particulièrement utile aux géologues d'exploration, aux planificateurs de la mise en valeur des ressources et enfin aux personnes intéressées aux gisements de molybdène.

INTRODUCTION

MOLYFILE was initiated in 1973 to serve as a simple, index-level computer file of molybdenum deposits and occurrences in Canada. It was constructed to be a source of data for reports, maps, and resource studies. Currently, the file contains data on about 2240 deposits and occurrences, and most public documents with molybdenum occurrence information have been reviewed up to the end of 1980. An early version of MOLYFILE was described by Prasad et al. (1974). Because of changing needs and data management systems, MOLYFILE has undergone fairly continuous evolution. The numerous changes in the file make it necessary to describe the latest version used to produce this report.

MOLYFILE was established before CANMINDEX (Canadian Mineral Occurrence Index) (Picklyk et al., 1978) and unfortunately lacks important features that CANMINDEX contains, such as the entity coded and information on how the entities were located, map references, bibliography, and comments on geologic characteristics. Nevertheless, it possesses some advantages, such as classification designed specifically for molybdenum deposits, geological age of the deposit if available, and production and reserve information.

Acknowledgments

Many individuals contributed data and helped with the construction of this file. D.F. Garson and K. Shewbridge were particularly helpful in obtaining numerous, varied computer plots and listings. D.F. Garson also made modifications to the file and wrote programs for data input and updates. R.M. Laramée was responsible for design of much of the present version of the file and has written numerous computer programs for data input, updates, retrievals, report generation, plotting, and data manipulation. W.N. Houston wrote and tested computer programs for an earlier MARS version of MOLYFILE (Prasad et al., 1974). J.J. Carrière assisted with data compilation and aspects of file construction.

Many corporate, provincial, and other federal government geologists generously provided data on deposits and occurrences.

DESCRIPTION OF FILE

Figure 1 is the most recent coding form used for data entry. Part "A" is the main body of the file and can be entered only once, whereas, Part "B" is for production and reserve information and can contain up to 99 production and 99 reserve figures.

ACCESSION NUMBER is a 6-character, numeric field that contains a unique number for each molybdenum deposit or occurrence. The first three digits are the National Topographic System primary quadrangle and the last three digits are a unique occurrence number for that particular NTS area.

NAME is a 34-character, free format, left justified, alphanumeric field. Alternate names are in brackets or separated by commas.

PROVINCE is a 5-character, fixed format, left justified, alphabetic field for political province or territory (with the Labrador part of Newfoundland distinguished from the Island part). The following codes are possible in this field: NFLD., LABR., N.S., N.B., QUE., ONT., MAN., SASK., ALTA., B.C., NWT., or YUKON.

GEOLOGICAL PROVINCE is an 11-character, fixed format, left justified, alphabetic field that can contain the following entries: APPALACHIAN, ARCTIC PFM., BEAR, CHURCHILL, CORDILLERAN, GRENVILLE, NAIN, SLAVE, SOUTHERN, or SUPERIOR.

Figure 1. *MOLYFILE coding form.*

NTS is a 6-character, fixed format, full, alphanumeric field for the National Topographic System that includes first the primary quadrangle (3 digits), second the secondary quadrangle (1 letter), and third the tertiary quadrangle (2 digits).

LATITUDE and LONGITUDE are 6- and 7-character, numeric fields for degrees, minutes, and seconds of latitude and longitude. UTM zone, northing, and easting have not been included because they can be calculated from the latitude and longitude. Where possible, locations were checked, but in many instances they could not be verified. The user is cautioned that some locations may be erroneous (revisions are welcomed).

LOCATION SOURCE is a 16-character, alphabetic field to indicate the nature and quality of location information. Until recently, this was a fixed format field that only accepted the following entries: FROM 24000 MAP, FROM 50000 MAP, FROM 125000 MAP, FROM 250000 MAP, FROM 1000000 MAP, FROM CANMINDEX, FROM MDS (Mineral Development Sector), FROM GEOSC-INDEX (Geoscience Index), MIN MAP LAB 325 (Mineral Map of Labrador), MAP O.F. NFL 888 (Open File NFLD – Mineral Occurrences of Newfoundland), QUE MIN OCC FILE (Quebec Mineral Occurrence File), MAN. MIND FILE (Manitoba Mineral Deposit File), BCMI MAP (British Columbia Mineral Inventory Map), RELIABLE PUBL, RELIABLE SOURCE, or UNRELIABLE. However, this is now a free format field where the actual source document is indicated.

AGE 1 and 2 are 8-character, alphabetic fields for geological age of the deposit. Only AGE 1 field is used if one age period designates the age but AGE 1 and AGE 2 fields are used to indicate a range of possible age. The following codes for time periods are acceptable in the AGE fields: PREC, ARCHEAN, PROT, APHEB, HELIKIAN, PALEOHEL, NEOHEL, HADRY, CAMB, ORD, SIL, DEV, MISS, PENN, CARB, PERM, TRIAS, JURAS, CRET, TERT, and QUATER.

DEPOSIT TYPE is a 2-character, numeric field accepting numbers ranging from 01 to 12 representing the following deposit types: (01) MAGMATIC, (02) GRANITIC PEGMATITE-APLITE, (03) SYENITIC PEGMATITE-APLITE, (04) SKARN, (05) PORPHYRY, (06) VEIN/REPLACEMENT, (07) VOLCANIC EXHALATIVE, (08) GRENVILLE SKARN (regionally distributed, metasedimentary, pyroxenitic rocks in the Grenville Supergroup), (09) UNCERTAIN METAMORPHIC, (10) SEDIMENTARY, (11) SUPERGENE, or (12) UNCLASSIFIED. For elaboration on the classification see Vokes (1963) and Kirkham (1972a,b). Kirkham (1972a) presented a classification for copper deposits, but most of the suggested classes and their inferred genesis are consistent with classes used here for molybdenum deposits.

SIZE ESTIMATE is a 1-character, numeric field accepting numbers ranging from 1 to 5 representing the following size classes: (1) >1 000 000 metric tonnes contained Mo, (2) 100 000-1 000 000 tonnes contained Mo, (3) 10 000-100 000 tonnes contained Mo, (4) 1000-10 000 tonnes contained Mo, and (5) 0-1000 tonnes contained Mo. Classes (1) deposits, which are large by global standards, to date have not been identified in Canada. In making these estimates all available data were used and the entire deposit was considered including clearly subeconomic molybdenum. The size designations, therfore, are crude estimates based on available data of the total amount of molybdenum contained in the geological entity. They have been used primarily for controlling symbol sizes plotted on distribution maps (see Map 12-1982, Kirkham et al., 1982).

MAJOR AND MINOR COMMODITIES, each are recorded in six 6-character, alphabetic fields that accept the following codes: AG (silver), APAT (apatite), AS (arsenic), ASB (asbestos), AU (gold), BA (barite), BE (beryllium), BI (bismuth), CD (cadmium), CO (cobalt), CORUND (corundum), FE (iron), FELS (feldspar), FLUOR (fluorite), CU (copper), GA (gallium), GRAPH (graphite), IN (indium), LI (lithium), MO (molybdenum), NB (niobium [columbium]), NI (nickel), PB (lead), PYRT (pyrite), RE (rhenium), REE (rare earth elements), S (sulphur), SB (antimony), SE (selenium), SN (tin), SR (strontium), TA (tantalum), TE (tellurium), TH (thorium), TI (titanium), U (uranium), V (vanadium), W (tungsten), and ZN (zinc). Other codes can be added if necessary. Major commodities have been distinguished from minor commodities on the basis of their relative economic values. The distinction in most cases was somewhat arbitrary and no ratios were adhered to rigidly. For many occurrences information required to distinguish major from minor commodities is not available. For such occurrences, and where commodities have equal status, the commodities have been entered in the major commodity field, even though the occurrence itself may be minor.

STATUS consists of two 16-character, fixes format, left justified, alphabetic fields to indicate the current status of the property, as it pertains to molybdenum. The status fields accept the following terms: PAST PRODUCER, PRODUCER, RESERVES KNOWN, INVESTIGATED DEP, or OCCURRENCE. The second status field is used only for past producers that still have reserves or demonstrated resources.

REFERENCE is a 45-character, free format, left justified, alphanumeric field to accommodate abbreviated references for the main sources of information in Part "A" of the file. It is not included in the present publication because it was, until recently, a fixed format field with very limited data meant for internal project use only.

CANMINDEX NUMBER is a combination of 6- and 2-character, right justified, numeric field to accommodate the unique CANMINDEX (Canadian Mineral Occurrence Index) link number (Picklyk et al., 1978). The first 6 digit field refers to the Indexed Mineral Deposit and the latter 2 digit field designates subdivisions or components of the deposit, such as distinct orebodies, ore zones, or separately owned parts of the deposit. This field, to link MOLYFILE with CANMINDEX and related files, has not yet been completed.

CODER, YEAR, MONTH, UPDATED BY, YEAR, and MONTH are fields that have been added recently but, like the CANMINDEX NUMBER field, at present do not contain any data.

Part "B" of MOLYFILE, which contains production and reserve information, was patterned after a coding form designed for copper deposits in Canada. At the time of preparation of this report, only 5 production and 5 reserve figures could be entered for a given deposit, but a separate library capable of containing 99 production and 99 reserve figures has been added to the file. The production and reserve files for copper and molybdenum deposits have been made identical so that, for coproduct and byproduct copper and molybdenum deposits, coded information will be entered automatically into both files. All reasonable, nonconfidential grade and tonnage figures available for Canadian molybdenum deposits have been coded as "reserves", without consideration of the economics of the deposit. Some of these "reserves" are clearly subeconomic and poorly defined and, therefore, should be considered "demonstrated" or "subeconomic" resources rather than reserves.

RANK is a 1-character, numeric field that will accept numbers ranging from 1 (reliable) to 5 (unreliable) for rating grade and tonnage figures. The distinction between reliable and unreliable data is based only on the subjective evaluation of R.V. Kirkham.

Figure 2. *Typical listing for deposit with production and reserves.*

Either metric tonnes or short tons can be entered into the file but to save space the data are stored only as metric tonnes. The conversion factor is 1 metric tonne = 0.90718474 short tons.

PRODUCT is a 1-character field that accepts the following codes: 0 (ore milled, or ore mined if ore milled is not available), C (concentrate produced), or M (refined metal produced).

%MO field will accept up to 4 digits after the decimal. Although this number of digits is not significant, many companies report per cent MoS_2 rather than per cent Mo and 4 digits after the decimal are necessary to calculate back from the stored per cent Mo values to quoted per cent MoS_2 values. The conversion factor used in calculations is 0.6 (%MoS_2) = %Mo.

Either GRAMS AU/TONNE or TROY OUNCES AU/TON and either GRAMS AG/TONNE or TROY OUNCES AG/TON can be entered into the file. The values, however, are stored only as GRAMS/TONNE. The conversion factor used for calculations is 1 troy ounce/short ton = 34.285724 grams/metric tonne.

COMMENTS is a 45-character, free-format, alphanumeric field for additional or qualifying information on production and reserve figures. Such information as grades of other commodities (e.g. bismuth, tungsten, or uranium), cut-off grades, ore zone name or designation (e.g. no. 5 zone or high-grade zone), reserve qualifiers (e.g. proven, probable, possible, drill indicated, geologic, or estimated), or additional production information (e.g. refined base or precious metals recovered, or other metals recovered, such as bismuth or rhenium) is put in this field.

REFERENCE is a 45-character, free format, alphanumeric field to indicate the source of the production or reserve information. Where necessary abbreviations such as BR (Branch), CIM (The Canadian Institute of Mining and Metallurgy), CMHB (Canadian Mines Handbook), CMJ (Canadian Mining Journal), EMR (Department of Energy, Mines and Resources Canada), GSC (Geological Survey of Canada), MJ (Mining Journal), ML (Mines Limited), NM (Northern Miner), NMI (National Mineral Inventory), ODM (Ontario Division or Department of Mines), QDNR (Quebec Department of Natural Resources), and WM (Western Miner) have been used.

DESCRIPTION OF LISTINGS

The computer listings from MOLYFILE presented in Appendices 1 to 3 of this report have been designed for maximum legibility and for rapid retrieval of index-level information. A typical listing from the main body of the report (Appendix 2) is given in Figure 2. In Appendices 1 and 2, the deposits are listed by accession number, a combination of NTS primary quadrangle (first number) and occurrence number within the quadrangle (e.g. 22-17, Fig. 2). Missing accession numbers in Appendix 3 (e.g. 105-1 to 3) indicate that, for one reason or another, entries have been deleted from the file. The main name is followed by alternate names in brackets. The major commodities are listed first, followed by minor commodities in brackets. "LOCATION SOURCE" could be potentially misleading, since it is a fixed format field with a limited number of possible entries that may not indicate the actual source of the location information (see previous setion under "LOCATION SOURCE"). The main function of this item is to give the user a general idea of the nature of the source of the location and its possible accuracy. For production and reserve figures that have been designated ranks 3 to 5 (see previous section under "RANK"), the statement "DATA OF QUESTIONABLE RELIABILITY" is printed at the end of the COMMENTS field. In some cases, perhaps only part of the figure (e.g. Mo or Au grade) is considered to be of questionable reliability, but this statement should caution users about the validity of aspects of the data.

CONCLUSIONS

MOLYFILE contains much valuable, index-level data on a wide spectrum of molybdenum deposits and occurrences in Canada and is the first national-scale, computer-processable file produced for molybdenum deposits and occurrences. It has, however, some serious weaknesses such as the lack of proper reference data. Nevertheless, MOLYFILE should serve as a useful, broad, shallow base from which more comprehensive, special purpose files can be constructed. The Geological Survey of Canada would be pleased to receive additional information, revisions, advice, and comments on this file.

---

[1] All reasonable, non-confidential grade and tonnage figures have been included without consideration of the economics of the deposit. Some of these "reserves" are clearly subeconomic and poorly defined and, therefore, should be considered "demonstrated" or "subeconomic" resources rather than reserves.

```
